ABSTRACT: Invitro screening using the dual culture technique was undertaken to assess the potential of seven Trichoderma species. Trichoderma viride, Trichoderma lignorum, T.album, T.hamatum, T.harizanum, T.glaucum and T.koeningi as biological control agents against Sheath rot fungus Sarocladium oryzae. The test organisms were isolated from the paddy field where the disease occurred. Results revealed that all the test antagonists effectively checked the growth of the pathogen. The test antagonists grow faster than the pathogen and produced inhibition zones thereby limiting the growth of the pathogen. In solid medium, Trichoderma harizanum was the most antagonistic organism under the conditions of this study. The culture filtrates of the test fungi also inhibited the growth of Sarocladium oryzae with Trichoderma harizanum showing the highest percentage inhibition (79%) and T.viride and T.lignorum (78%). T.harizanum culture filtrate showed the highest percentage growth inhibition at 15% concentration in Sarocladium oryzae while T.viride and T.lignorum filtrates showed inhibition at 25% respectively.

Key words: Invitro, antagonism, Trichoderma harizanum, inhibition.
MATERIALS METHOD

Organisms

Sheath rot fungus (*Sarocladium oryzae*) was isolated from paddy field of Thanjavur district. Antagonistic fungus (*Trichoderma viridae, T.lignorum, T.album, T.harizanum, T.hamatum* and *T.koenigi*) were taken from TNAU, Coimbatore. Both these cultures of pathogens and the antagonist were maintained on Potato dextrose Agar.

TEST OF ANTAGONISM INVITRO

Dual culture technique:

Inhibition of pathogen growth by these test antagonists was carried out on Potato dextrose Agar medium using the dual culture technique. Five millimeter diameter mycelia plugs of each test antagonist were placed at the periphery of three different culture plates and incubated for 3 days at 28±2ºC (Evans *et al.*, 2003). After three days each plate was doubly-inoculated with another 5mm diameter mycelia plug of the pathogen placed 5cm from the test antagonist. The dual culture plates were incubated for additional 9 days at 28±2ºC. In the control experiment, the test antagonists were replaced with sterile agar plugs. The growth of the pathogen in both the test and control experiments were recorded. Data were obtained for the Percentage inhibition of radial growth (100x(R1-R2)/R1) where R1= radial growth of the pathogen in control and R2= radial growth of the pathogen in dual culture with antagonist) and the width of the zone of inhibition (ZI)(measured as the smallest distance between the colonies in the dual culture plate) (Royse and Ries, 1978, Garrett, 1956). Five types of interaction grades as proposed by Skidmore and Dickinson (1976) have been used. Results were recorded in the (Table 1& Plate I).

CULTURE FILTRATE ASSAY

One hundred milliliters (100ml) of potato dextrose broth (PDB) were dispensed into separate 250-Erlenmeyer flasks and inoculated with 5mm-diameter discs from the edge of 7 day old cultures of the test antagonists maintained on PDA. Each flask was inoculated with three discs and the set up incubated at 28±2ºC for 7 days. Culture filtrates were harvested by filtering through Whatman No.1 filter papers and finally through Millipore filter (0.45µm) to obtain sterile culture filtrate. The culture filtrate was adjusted to pH 5.6 by using 0.1N HCl or 0.1N NaOH before use. Different concentrations viz., 5, 10, 15, 20 and 25 % of the culture filtrate were mixed with cooled Potato Dextrose Agar before plating. The medium devoid of culture filtrate served as control. Petridishes were inoculated separately with a 9mm agar disc of the tested pathogens, cut from actively growing colony of 5 days old culture, and incubated at 28±2ºC. The radial growth of tested pathogens was measured after 24 hours intervals.

RESULTS AND DISCUSSION

Antagonism in culture:

Results showed that all the fungi tested in this study exhibited antagonistic activities against sheath rot fungi *Sarocladium oryzae*. Radial growth of the pathogen was considerably hindered by all the test antagonists under the conditions of this study. *T. harizanum* was the most antagonistic and inhibited the radial growth of the pathogen most while *T.album* was the least antagonist.

Effects of culture filtrate on antagonism:
Culture filtrates of the fungi tested in this study showed inhibitory effect on the growth of the pathogen. Growth inhibition was found to increase with the period of incubation (Table 2). *T.harzianum* culture filtrate showed maximum percentage of inhibition at 15% while *T.Viride* and *T.lignorum* filtrates produced 25% inhibition, respectively.

DISCUSSION

Previous studies have demonstrated that before mycelia of fungi interact, *Trichoderma* sp. produces low quantities of extracellular exochitinases (Kullnig *et al*.,2000., Brunner *et al*., 2003). The diffusion of these enzymes dissolves cell fragments of host cells. These cell fragments in turn induce the production of further enzymes and trigger a cascade of physiological changes, stimulating rapid and directed growth of *Trichoderma* sp. (Zeininger *et al*., 1999). In the present, invitro studies have demonstrated that due to chemotropism hyphae of *Trichoderma harzianum* can grow and branch directly towards the host.

The idea of a sustainable agricultural practice and environmental protection enhances the importance of biocontrol. The adoption of a sustainable agricultural practice, using strategies that are environmentally friendly, less dependent on agricultural chemicals is gaining worldwide recognition. One of the key elements of such sustainable agriculture is the application of biocontrol agents. *Trichoderma* sp. is antagonistic by nature with rich resource and a broad action scope. The present study addresses the effective control mechanisms of *Trichoderma harzianum* against the sheath rot pathogens. The observation is similar to the findings of Tronsmo and Dennis (1977) and Okigbo and Ikediagwu (2000) in their investigation on the effects of *T.viride* on post harvest Botrytis rot of strawberry and yam rot, respectively.

Panneerselvam and Saravananmuthu (1996) had reported that antagonistic interaction of some soil fungi namely, *Aspergillus candidus*, *A.flavus*, *A.fumigatus*, *A.nidulans*, *A.niger*, *A.sulphureus*, *A.terreus*, *A.variecolor*, *Gliocladium* sp. *Penicillium citrinum*, *P.fumiculosum* and *Trichoderma viride* against *Sarocladium oryzae* was studied. The maximum percentage inhibition of growth with *S.oryzae* with *Trichoderma viride*, followed by our study *Trichoderma* sp. used for antagonist against *Sarocladium oryzae*.

Tondje *et al*.,(2007) had reported that *Trichoderma asperellum* isolates controlled cocoa black pod caused by *Phytophthora megakarya* in Cameroon. Many beneficial fungi and bacteria that occur naturally and associated with coca were reported to show potential as antagonists of major cocoa pathogens (Bong *et al*., 2000., Samuel and Habber, 2003).

Our, result explains that significant success in biocontrol is achieved under invitro conditions. Even though more research is needed to understand the antagonistic mechanism, improvement of strains and development of supplementary products of biocontrol agent for restraint of pathogens. Thus, it is noticeable that a microbial biocontrol agent offers harmless to the animals and human beings, cheaper than chemicals and highly effective.There is no risk of the pathogens develop resistance, fungicide residues in food and ground water.
